Japan Experience Dashboards

Reducing Operational Risk, Improving Signal Quality, Enabling Proactive Action

ETS Japan | 2026 Objectives

March 13, 2026

Manulife

INTERNAL

Executive Summary

This initiative establishes two complementary dashboards—**Employee Experience (Production)** and **Developer Experience (Non-Production)** - to reduce operational risk, improve signal quality, and strengthen executive confidence in Japan operational readiness.

From an ETS 2026 perspective, this directly supports:

- **Robust Technical Core** by improving early risk detection, observability maturity, and monitoring signal quality
- **Outstanding Colleague Experience** by ensuring employees and developers have clear, reliable visibility into the health of the applications and environments they rely on
- **AI-Powered Organization** by creating high-quality, structured signals that can be enriched, correlated, and leveraged for proactive insights over time

The intended outcome is that leadership has a **clear, defensible view of Japan readiness before the business day begins**, reducing reactive escalations, ambiguity, and noise while increasing confidence in operational health.

Employee Experience Dashboard (Production)

- Single, authoritative view of application availability and performance from a Japan employee perspective
- Coverage across Bronze, Silver, and Gold applications, including international dependencies
- Daily readiness confirmed before 8:00 AM JST to reduce executive escalations and reactive noise
- Success: Reduced leadership escalations and 100% coverage of employee-facing URLs

Developer Experience Dashboard (Non-Prod)

- Holistic view of non-production environment health for developers and testers
- Eliminates time lost discovering environment issues before work begins
- Daily pre-8:00 AM JST readiness visibility for non-production environments
- Success: Reduced environment-related delays and proactive issue identification

Employee Experience Dashboard (Production)

The Employee Experience Dashboard focuses on production applications from a Japan employee's point of view, not purely infrastructure or system metrics.

Key objectives:

- Provide a **single authoritative** view of application availability and performance for all employee-facing services used in Japan
- Cover **Bronze, Silver, and Gold** applications, including critical international dependencies that materially impact Japan employees
- Ensure visibility **spans URLs, underlying components, and alert routing**, aligned with Manulife's observability maturity standards

A core operational goal is to enable a daily readiness confirmation before 8:00 AM JST, so that issues are known, contextualized, and owned before employees begin work.

By improving signal quality and clarity, we expect to:

- **Reduce** unnecessary escalations to senior leadership
- **Minimize** reactive, ad-hoc inquiries
- **Provide** a defensible, data-driven narrative when issues do occur

Success is measured not just by coverage, but by reduced executive noise and increased confidence in Japan operational readiness.

Developer Experience Dashboard (Non-Production)

The Developer Experience Dashboard addresses a different—but equally critical—problem**: time lost discovering non-production environment issues.**

Today, developers, testers, and support teams often lose productivity determining whether an issue is code-related or environment-related. This dashboard aims to eliminate that uncertainty.

Key objectives:

- Provide a **holistic view of non-production environment health**, including availability of URLs and critical underlying components
- Make it immediately clear whether an environment is healthy or degraded, reducing time spent on diagnosis
- Establish a **daily pre-8:00 AM JST** non-production readiness check, so issues are surfaced and owned before they block work

From an ETS service quality perspective, this shifts non-production support from reactive discovery to **proactive visibility**, improving trust and efficiency for the developer community.

Success is defined by:

- Measurable reduction in time lost to environment investigation
- Improved developer and tester productivity
- Earlier identification of non-production issues that could otherwise delay testing or releases
